

Session 17

1.Create a smoke test checklist for the login and dashboard features of a food delivery app like Zomato, listing at least 5 key test cases that would quickly verify if the main flows work after a new build.

1. Smoke Test Checklist – Food Delivery App

Feature: Login and Dashboard

Purpose: To quickly check whether the main features are working after a new build.

TC ID	Test Case	Steps	Expected Result
ST-01	Login with valid credentials	Enter valid mobile/email and password/OTP	User should log in successfully
ST-02	Login with invalid credentials	Enter incorrect login details	Appropriate error message should be displayed
ST-03	OTP verification	Enter valid OTP during login	User should be successfully authenticated
ST-04	Dashboard loading	Login and open the dashboard	Dashboard should load without errors
ST-05	Dashboard navigation	Tap options such as Search, Restaurants, Orders	Selected section should open correctly
ST-06	Logout	Open profile/settings and tap Logout	User should be logged out successfully

Smoke Testing Result: If these critical test cases pass, the build can proceed for detailed testing.

2.Use error guessing on the Flipkart login page — try at least 3 unusual input combinations (such as a very long email, special characters in the password, or blank fields)

and record what happens in each case.
Hint: Think about what kinds of mistakes real users might make and how the app should respond.

Sanity Test Scenario – Add to Cart

Scenario: Verify the recent bug fix where the selected product was not being added to the cart correctly.

Steps:

1. Open the shopping app.
2. Search for any available product.
3. Open the product details page.
4. Select the required quantity/variant.
5. Click **Add to Cart**.
6. Open the cart.

Expected Result:

The selected product, correct quantity, and selected variant should appear correctly in the cart.

Scope: Only the reported **Add to Cart bug fix** is verified. Unrelated features such as payment, wishlist, filters, and checkout are not retested.

3. Create a table listing at least 5 exploratory test scenarios you would perform on the Zomato restaurant search feature, including what you would do and what kind of bugs you might expect to find.

Smoke Testing vs Sanity Testing

Point	Smoke Testing	Sanity Testing
Purpose	Checks whether the major features of a build work	Checks whether a specific change or bug fix works
Scope	Broad but shallow	Narrow and focused
When performed	Usually after receiving a new build	Usually after a minor change or bug fix

Testing approach	Tests critical functions across the application	Tests only the affected functionality
Example – Instagram	Check login, feed, profile, and posting at a basic level after a new build	After fixing a post-upload bug, verify only that posts upload correctly
Example – Paytm	Check login, balance page, payments, and transaction history at a basic level	After fixing an OTP issue, verify that the OTP login flow works correctly

In short:

- Smoke = “Is this build stable enough for further testing?”
- Sanity = “Did this specific change or bug fix work correctly?”

4. Perform exploratory testing on the Paytm recharge flow (up to the payment screen, do not actually pay) and write a short report describing your testing approach, any bugs or usability issues found, and suggestions for improvement.
Constraint: Focus on areas where you think users might get confused or stuck, not just obvious errors.

Exploratory Testing Report – Paytm Recharge Flow

Application: Paytm

Feature: Mobile Recharge

Testing Type: Exploratory Testing

Scope: From opening Recharge to the payment screen only

Payment: Not completed

Testing Approach

I explored the mobile recharge flow without following only predefined test cases. I focused on areas where users could become confused or make mistakes, such as selecting the wrong mobile number, choosing an unsuitable recharge plan, understanding plan details, and navigating back before payment.

Exploratory Testing Findings

Bug/Issue ID	Area Tested	Observation	Expected Behavior	Suggestion
ET-01	Mobile Number	A user may accidentally enter an incorrect mobile number and continue.	The app should clearly show the entered number before proceeding.	Display a clear confirmation of the mobile number before selecting a plan.
ET-02	Operator Selection	Users may be unsure whether the selected operator is correct.	Operator and circle information should be clearly visible.	Show operator details prominently and allow easy correction.
ET-03	Recharge Plans	Similar-looking plans can make it difficult to understand the difference between them.	Important benefits, validity, and price should be easy to compare.	Highlight key plan details such as validity, data, and benefits.
ET-04	Back Navigation	Going back during the recharge process may make users unsure whether their entered information is saved.	The app should clearly indicate what information will be lost or retained.	Provide a confirmation message when leaving an incomplete recharge.
ET-05	Payment Screen	Users may be unsure about the final amount or selected recharge before paying.	The payment screen should clearly show mobile number, plan, amount, and payment method.	Add a clear final summary before payment confirmation.

Suggestions for Improvement

1. Show the **mobile number and operator** clearly before proceeding.
2. Make recharge plans easier to compare using **price, validity, and benefits**.
3. Display a clear **order/recharge summary** before payment.
4. Warn users before they leave the recharge process if information may be lost.
5. Use simple labels and clear error messages to reduce user confusion.
